Abstract—This proposal introduces Team 2's idea for the 2023-2024 Capstone Design Project. The following proposal introduces the project, formulates the problem, and surveys the solutions. The measures of constraints, specifications, potential obstacles, and resources are also included.

Keywords— Greenhouse, motors, sensors, zones, temperature, humidity, PLC

I. INTRODUCTION

In a world where climate change poses an increasing threat to crop production, there is an innovative solution that is readily sustainable and efficient. Team 2 proposes to design and build an automated greenhouse system for the Agricultural Department at Tennessee Technological University.

There are many benefits of a greenhouse compared to outdoor farming. "The advantages of protected cultivation compared to outdoor production of vegetables have a mostly better product quality with higher input efficiencies of water, nutrients and crop protection agents" [1]. A greenhouse also allows for year-round crop growing, while outdoor farming has certain limitations depending on the weather season.

The objective of Team 2's project is to provide the necessary tools and equipment to allow the greenhouse at Oakley Farms to monitor and control the different aspects of the building. This certain greenhouse will be used specifically for ferns and shrubs. By achieving this goal, the Agricultural faculty and students will be able to prioritize their labor to other greenhouses that require more attention. In the upcoming sections, the problem formulation will be described, which will include the following: background information, specifications for the project, constraints, and the standards that will need to be considered. Some formulated solutions and researched solutions will then be

outlined. Finally, the team skills, budget, and timeline will be shown.

II. FORMULATING THE PROBLEM

A. Background

The term "greenhouse" has been around for centuries with records dating back as far as 14 CE in Rome; however, modern greenhouse concepts did not begin to appear until around the 20th century. There are also several different versions of the greenhouse including, but not limited to: the Venlo-style, the Westland-style of the Netherlands, and Parral-type. In the southern region of the United States, as well as other warm regions of our country, the arch-style greenhouse that are gutterconnected and have a plastic film covering the exterior have become the most popular [2]. The greenhouse that Team 2 proposes to automate is one of such arch-type greenhouses with plastic coverings around the edges of the house itself. The house is heated and cooled via a system of fans and heaters connected to a thermostat measuring device. The outer plastic of the greenhouse is either rolled up or down via a hand-crank motor that must be physically turned to make the plastic roll. The house also contains a "carbon dioxide burner" or a carbon dioxide generator that is used to supply carbon dioxide to the various plants within the house. These current features of the greenhouse are very labor intensive and require the Agricultural faculty and students to monitor the temperature of the house as well as the need for the plastic shell to be either raised or lowered. The greenhouses located at the Oakley farm facility are separated into two planting "zones" in which different plants can be grown, tomatoes and peppers for example. The greenhouse that Team 2 proposes to automate is planned to be split into four of these zones for separate plant growth. With the world population projected to reach 2050 by the Food and Agriculture

Organization, automation of safe and sustainable agricultural practices is becoming more and more paramount [3].

B. Specifications

This proposal includes specific requirements desired by TTU's Agricultural Department, which is the customer for the project. The first specification revolves around the hand-cranked motor used to raise or lower the plastic flaps. Team 2 will implement an electric motor in place of the manual crank, which will also be controlled by a sensor to open or close the flaps depending on the temperature in the greenhouse. Next, the fans in the greenhouse will also be controlled by a sensor to turn on after a certain temperature is reached.

There will be zones created in the greenhouse to control the nutrient levels and water levels for the shrubs and ferns. A manual override for the water levels will be implemented in case there is a need for more watering of certain plants.

Sensors will be placed throughout the greenhouse to accurately measure temperature, humidity, and carbon dioxide (CO2) levels.

In each of the zones, there will be containers for the shrubs and ferns. Sensors will be placed into these containers to measure the nutrient levels and moisture levels. This will provide an accurate measurement to each plant to ensure they are healthy.

Table 1: Greenhouse Item Specifications		
Item	Specifications	
Motor	Motor shall roll up plastic flaps once the temperature in the greenhouse exceeds 75°F.	
Zones	Greenhouse shall contain four separate zones.	
Fan Control	Fans shall turn on once the greenhouse temperature exceeds 85°F.	
CO ₂ Level	Sensors shall alert if carbon dioxide levels reach below 800ppm or above 1200ppm.	
Humidity Level	Sensors shall alert if humidity levels are not within set range, usually 50-80%.	
Water Control	Interface shall be able to offer customizable amount of scheduled waterings per day as well as manual overrides for watering.	
Nutrient & Moisture Levels	Sensors shall alert if nutrient and moisture levels are not in ideal range.	

The greenhouse system specifications cover a wide array of features that aim to create the perfect conditions for plant growth and care. It all starts with temperature control: when the

greenhouse temperature climbs above 75°F, a motor kicks in to roll up plastic flaps, helping to cool things down. To keep things comfortable for the plants, fans start up when the temperature exceeds 85°F, ensuring good ventilation. The greenhouse is divided into four zones, and each one can be tailored to suit different types of plants. Air quality is a priority too, thanks to CO2 sensors that keep an eye on carbon dioxide levels. They'll send out alerts if CO2 drops below 800ppm or rises above 1200ppm.

Maintaining the right moisture and humidity levels is critical, and humidity sensors will let you know if things stray from the 50-70% range. This will also allow you to have your say with water control interfaces, allowing you to set up scheduled waterings and make manual adjustments. Finally, nutrient and moisture sensors keep plants thriving by issuing alerts if levels aren't where they should be. Together, these specifications make sure the greenhouse provides the best possible environment for the plants.

C. Constraints

User Interface must be understandable and have ease of use for this project to truly be complete. Many hands and users will be involved with using the interface and they may or may not know what has and has not been done within the greenhouse within a recent period. They will also need to understand clearly what each option means so they do not click something that shouldn't be used on the plants at a certain time or for a total amount of times. We can test the ease of use by surveying the people who will be hands on with the devices once installed.

Time is a big constraint as we have a customer and a sponsor who will be expecting a working product. We will continue to revise and improve our project as the hard deadline of two semesters is our overall timeline.

We also have a constraint of at least two zones in the greenhouse and are hopeful for four total once the project is completed. This includes a total structure of the greenhouse being split into at least half, up to quarters, where each part can be monitored and controlled based on which sector it is in. They should all be separate and not have leaks of information from other sectors influencing the data.

We also have a project budget that will be a constraint that includes approximately \$1,300 in materials and work to conclude the project.

All constraints must follow and be aware of the standards when using ad working with motors and electrical work including safety concerns and hazards. Therefore, Team 2 must strive and follow all statements in the 'Standards' section of this proposal.

D. Standards

Electronics

- IEEE 1547 Standard for Interconnecting Distributed Resources with Electric Power Systems
- IEEE 1451.4 Standard for Smart Transducer Interface for Sensors and Actuators

- IEEE 2410 Standard for Distributed Energy Resources Interoperability and Communication
- 1926.404b OSHA Standard for Wiring Design and Protection
- 1910.133a OSHA Standard for Electrical Protective Equipment

Mechanics

- 1926.300b.2 OSHA Standard for Guarding from Rotating or Moving Parts of Equipment
- OSHA Section5(a)(1) Standard for Workspace Safety Free from Recognized Hazards
- 29 CFR 1910.1200 Standard for Hazard Communication
- 29 CFR 1910 Subpart S Standard for Electrical Safety
- 1910.133a OSHA Standard for Eye and Face Protection

Environmental

- ASABE S520 Standard for Controlled Environment Agriculture Facilities
- ASABE EP455.3 Standard for Design, Construction, and Performance of Evaporative Cooling Systems

III. SURVEY OF SOLUTIONS

A. Measures of Success

- Siding and Temperature Regulation: To save energy and money for the customer they have asked for motors to be added to the outside of the greenhouse which will roll the siding up. This will be regulated by sensors that measure the temperature inside. When the temperature reaches a set point, the siding will roll up or down based on what is desired. The measure of success is for the siding to be able to keep the house at the desired temperature based on the plant's needs.
- Manual Water Override: Based on certain conditions inside the house, the customer has requested that the watering schedule have the option to be manually operated. This is for two main reasons, the first being that sometimes the plants need to be watered extra due to certain outside factors. The other being that if there were to be an issue with the components, the plants would obviously still need to be watered. The measure of success is for the water to be controlled by the PLC but also able to be manually controlled.
- Ease of Use: It is imperative that the system is concise in the functions it can provide. A working and easy to follow control system for the automation is needed for evading mishaps towards the sheltered plants. The measure of success for the controls is not only correct functionality, but also a straightforward navigation path through these controls for the best possible usage of the system.

• Differences in Zones: Variety in the amount of water and nutrients for plants in the green house is expected by the customer. While 2 to 4 zones will suffice, 4 is the ultimate objective for group 2. The measure of success is for each zone to be able to independently fluctuate needs for water and nutrients.

B. Past Solutions

- One example of a past solution to the automated greenhouse problem is the Bluelab icons series of plant growth solutions. This collection of plant growth items includes pH and nutrient level sensors as well as a "scalable" kit that can measure pH and nutrient levels as well as set remote alarms and deliver set dosages of nutrients to desired plants. The kit itself is called the Bluelab "Autogrow Intellidose Kit." Bluelab is a company out of New Zealand who provide "flexible and scalable solutions" for commercial growers [4].
- Another past idea for the automated greenhouse is the Prospiant greenhouse automation system. Prospiant states that they provide an automated greenhouse system that provides a range of climate control systems that oversee temperature, humidity, carbon dioxide and light. The company also claims that these systems are used to create the ideal environment for crop growth and aim to reduce consumption of water, fertilizers, pesticides, and chemicals while also optimizing the use of manpower and crop growth and production. Prospiant also states that the upfront costs of such a system is a challenge to some growers, but the company claims that the long-run benefits far outreach the initial costs and worries [5].
- The company Priva has provided yet another solution to the automated greenhouse issue. Priva aims to provide a fully automated crop growth system that is completely remote and can be operated from the palm of one's hand with any cellular device. The company wishes to provide its customers with a solution that integrates and links all processes and systems in user greenhouses including, but not limited to irrigation, lighting, carbon dioxide levels, and plant nutrients. Priva states that its systems contribute to achieving desired climate conditions for greenhouses, help users to optimize their energy and water usage, providing fully remote capabilities and "futureproofing" its customers businesses [6].
- One final solution to the issue is the MVTEC software-based agriculture solution. The company aims to provide cost-effective resources, high quality and quantity of crop yields, and reduction of the environmental impact of greenhouses through its plant protection software and machinery. They are also looking to provide precise harvest times, availability, and reduction of harmful substances and plant diseases

with their automated monitoring and harvesting processes [7].

C. Potential Obstacles and implications

- The weather of the environment is particularly an obstacle that group 2 is to face. With the greenhouse being outdoors, the automated system should be able to withstand and continue to run in both high and low temperatures and withstand moisture. It is group 2's job to account for the range of temperatures and precipitation throughout the seasons and choose materials that will not fail from freezing, overheating, or showers.
- Pest and insects can cause a lot of issues for the greenhouse in which plants will not grow or produce as expected. This can cause destruction of plants or even prevent growth. Pest management can be quite useful as the remedy for this issue; however, research is highly suggested for the use of such products as pesticides.
- A power outage can cause the automation system to shutoff and no longer control required variables for plant growth. A backup power supply, via battery or generator, could help keep the greenhouse in check for as long as the power is out.
- The size of the greenhouse can possibly grow and with that so does the automation system. An obstacle that can arise is the ability to add on to the system to reach new additional areas or zones that have been installed
- Humans can only do so much when it comes to creating and normal wear and tear is bound to happen. Regular maintenance and repairs would have to be made, but the issue comes from being able to easily access the area in need of such tune-up.
- Proper airflow inside the greenhouse is essential in keeping the plants healthy. A potential hazard arises since the house only has two fans which could fail over time. This risk can be eliminated by having backup fans.

IV. RESOURCES

A. Team Members

The following list is meant to reflect the key proficiencies of each team member.

Jaxson Billings

- C/C#/C++
- Java
- Python
- Assembly
- Digital/Embedded Systems
- Debugging
- Welding

Jared Hooker

- Power Generation
- Power Distribution

- Soldering
- LTSPICE Simulations
- Electronics
- MATLAB
- Wiring

Grant Hooper

- Electronics
- MATLAB
- LTSPICE Simulations
- Soldering
- Wiring
- 3D Modeling (and 3D printing if necessary)
- EM Fields

Noah Jones

- Project Management
- Wiring
- Electronics
- Soldering
- MATLAB

Bryan Rhoton

- Digital/Embedded Systems
- C/C#/C++
- Python
- MATLAB
- LTSPICE Simulations
- Circuit Analysis
- Assembly
- Circuit Design

B. Components and Project Budget

- Items Needed (Tentative)
 - o Temperature Sensors (DHT11 or DHT22)
 - o Humidity Sensors (DHT11 or DHT22)
 - CO2 Sensor
 - o Soil Moisture Sensors
 - o pH and Nutrient Sensors
 - o Arduino/Raspberry Pi
 - Linear Actuator or Servo Motor
 - o Relay Modules
 - o Software Development Tools (Possibly)
 - Wiring
 - Connectors
 - o Tubing
 - o Contingency Plan
- Current Inventory
 - o Greenhouse Structure
 - Power Supply
 - Breadboard

Team 2 can expect to see a budget of approximately \$1,262.68 to be able to complete the autonomous greenhouse with a contingency plan of twenty-five percent included in the budget. The table below shows the projected cost of the Bill of Materials. These costs are not final and are only an expected amount per item. The item list is not final, and one can expect to see unpredicted materials not foreseen. Prices do not include

shipping as the total number of orders and total number of suppliers are not yet known. Items could also be provided by the customer or sponsor if applicable and available.

Table. Tentative Summary of Expected Project Costs			
Item	Cost (USD)	Link to Example	
Servo Motor	\$79.90	https://www.trossenroboti cs.com/dynamixel-mx- 12w-robot-actuator	
Temperature And Humidity Sensors	\$9.95 x 4	https://www.adafruit.com/ product/385

C. Timeline

This time can be split into the following sections provided by the course syllabus:

- Team Contract
- Project Proposal
- Conceptual Plan
- Conceptual Design
- Detail Design Phase
- Additional Course Due Dates

All dates below have been established by Mr. Roberts. Each subsection in the Gantt chart below has assignees based on skill sets and will be documented below:

Logic Design – Jaxson Billings and Bryan Rhoton Sensors & Parts Design – Jared Hooker, Grant Hooper, and Noah Jones

The Gantt chart is presented below. It is split into two figures. The first being the first half of the semester and the second figure representing the second half. All tasks have been spread out appropriately and should be adequate for completion as long as no unforeseen problems and conflicts occur. The final presentation is due on December 8th, 2023, and is the basis for all other deadlines.

Figure 1. Gantt Chart Representing 1st Half Semester Dates

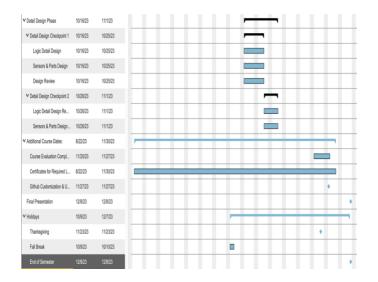

Figure 2. Gantt Chart Representing 2nd Half Semester Dates
